# TABLES OF CURVES WITH MANY POINTS 

Gerard van der Geer and Marcel van der Vlugt

#### Abstract

These tables record results on curves with many points over finite fields. For relatively small genus $(0 \leq g \leq 50)$ and $q$ a small power of 2 or 3 we give in two tables the best presently known bounds for $N_{q}(g)$, the maximum number of rational points on a smooth absolutely irreducible projective curve of genus $g$ over a field $\mathbb{F}_{q}$ of cardinality $q$. In additional tables we list for a given pair $(g, q)$ the type of construction of the best curve so far and we give a reference to the literature where such a curve can be found.

## 0. Introduction

In recent years the question how many points a curve of genus $g$ over a finite field $\mathbb{F}_{q}$ can have, has attracted a lot of attention. This was motivated partly by possible applications in coding theory and cryptography, but just as well by the fact that the question represents an attractive mathematical challenge.

It is well known that a smooth absolutely irreducible projective curve of genus $g$ over a finite field $\mathbb{F}_{q}$ can possess at most $q+1+2 g \sqrt{q}$ rational points. By a curve we shall mean in this paper a smooth absolutely irreducible projective curve defined over a finite field. The bound mentioned is the celebrated Hasse-Weil bound, proved by Hasse for $g=1$ and by Weil in general. We denote by $N_{q}(g)$ the maximum number of rational points on a curve of genus $g$ over $\mathbb{F}_{q}$. The Hasse-Weil bound implies

$$
N_{q}(g) \leq q+1+[2 g \sqrt{q}],
$$

where $[x]$ is the integer part of $x \in \mathbb{R}$.
After Weil proved his bound around 1940 the question how many rational points may lie on a curve over a finite field $\mathbb{F}_{q}$ remained untouched for many years. In 1980 Goppa came up with the beautiful idea to associate an error-correcting code to a linear system on a curve over a finite field, see [Go]. In order to construct good codes one needs curves with many points and thus Goppa's work led to a revival of interest in rational points on curves over finite fields. Applications in cryptography and recent constructions of quasi-random point sets also require curves with many points and added a further impetus to work in the field.

[^0]In 1981 Ihara showed in [I] by a simple and elegant argument that

$$
\begin{equation*}
N_{q}(g) \leq q+1+\left[\left(\sqrt{(8 q+1) g^{2}+4\left(q^{2}-q\right) g}-g\right) / 2\right] . \tag{1}
\end{equation*}
$$

For $g>(q-\sqrt{q}) / 2$ this bound is better than Weil's bound and gives the asymptotic bound

$$
\begin{equation*}
A(q):=\lim \sup _{g \rightarrow \infty} \frac{N_{q}(g)}{g} \leq \sqrt{2 q+\frac{1}{4}}-\frac{1}{2} \tag{2}
\end{equation*}
$$

Ihara also showed that if $q$ is a square one has $A(q) \geq \sqrt{q}-1$ using a sequence of modular curves. Refining Ihara's idea to derive (1) Drinfeld and Vladut proved that

$$
\begin{equation*}
A(q) \leq \sqrt{q}-1 \tag{3}
\end{equation*}
$$

In [S1] Serre started the investigation of the actual value of $N_{q}(g)$. One has $N_{q}(0)=q+1$. For $g=1,2$ there are explicit formulas for $N_{q}(g)$. From [S2],[S4] we quote the following result:
Proposition. Let $q=p^{m}$ and set $\mu=[2 \sqrt{q}]$. For $g=1$ one has $N_{q}(1)=q+1+\mu$, except when $m$ is odd, $m \geq 3$ and $p$ divides $\mu$, in which case we have $N_{q}(1)=q+\mu$. Similarly, for $g=2$ we have $N_{q}(2)=q+1+2 \mu$ except in the following cases:
i) $N_{4}(2)=10, N_{9}(2)=20$;
ii) $m$ odd, $p$ divides $\mu$;
iii) $m$ odd and $q$ of the form $x^{2}+1, x^{2}+x+1$ or $x^{2}+x+2$ for $x \in \mathbb{Z}$.

In the cases ii) and iii) we have $N_{q}(2)=q+2 \mu$ if $2 \sqrt{q}-\mu>(\sqrt{5}-1) / 2$ or $N_{q}(2)=q+2 \mu-1$ else.

For $g=3$ one can find the values of $N_{q}(3)$ in [S4] for $q \leq 19$ and in [T] for $q<100$.

In [S1] Serre used a little arithmetic to show that the Hasse-Weil bound may be sharpened to

$$
N_{q}(g) \leq q+1+g[2 \sqrt{q}] .
$$

In the same paper Serre introduced the idea of using a 'formule explicite' in analogy with number theory for obtaining a better upper bound for $N_{q}(g)$. Oesterlé used methods from linear programming to perfect this idea, see [S4]. The refinements of the Hasse-Weil bound by Ihara, Serre and Oesterlé were obtained by purely arithmetical considerations on the eigenvalues of Frobenius. For a curve $C$ over $\mathbb{F}_{q}$ of genus $g$ the difference

$$
\delta=(q+1+g[2 \sqrt{q}])-\# C\left(\mathbb{F}_{q}\right)
$$

is called the defect of the curve. By a combination of arithmetic and geometric arguments the non-existence of curves with small defect for a wide range of pairs $(g, q)$ was proved in a series of papers by various methods: $[\mathrm{F}-\mathrm{T}],[\mathrm{H}-\mathrm{L} 1, \mathrm{H}-\mathrm{L} 2],[\mathrm{K} ̈]$, [K-T], [L2], [L3], [Sa], [S4], [S-V].

In the tables we shall use as upper bound for $N_{q}(g)$ the best bound that the estimates of Hasse-Weil, Ihara, Serre and Oesterlé provide combined with the sharpenings coming from the papers just mentioned.

In order to test how good these bounds really are one tries to come as close to these bounds as one can by constructing curves with as many points as possible.

With an eye towards feasibility of applications it is important to have such curves in a form as explicit as possible.

The methods used for the construction of curves with many points are rather diverse, but roughly speaking one can distinguish the following approaches:
I. Methods from general class field theory;
II. Methods from class field theory based on Drinfeld modules of rank 1;
III. Fibre products of Artin-Schreier curves;
IV. Towers of curves with many points;
V. Miscellaneous methods such as:

1) formulas for $N_{q}(1)$ and $N_{q}(2)$;
2) explicit curves, e.g. Hermitean curves, Klein's quartic, Artin-Schreier curves, Kummer extensions, complete intersections or curves obtained by computer search;
3) elliptic modular curves $X(n)$ associated to the full congruence subgroups $\Gamma(n)$;
4) quotients of curves with many points.

Methods from general class field theory exploit subfields of Hilbert class fields or more generally of ray class fields of the function field of a given curve $C$ in which a substantial number of the rational points of $C$ split completely. General class field theory is a powerful weapon, but has as its drawback that often it produces a mere existence result and not an explicit curve.

Employing properties of Drinfeld modules of rank 1 in the case where the base curve $C$ is the projective line $\mathbb{P}^{1}$ one can produce good subfields of cyclotomic function fields which have the advantage of being explicit. For general base curves the curves produced correspond to subfields of narrow ray class fields and explicit forms of these function fields are then much harder to find.

The fibre product method yields defining equations for the curves thus constructed. In the category IV one finds mainly towers consisting of a combination of Kummer and Artin-Schreier extensions or composita of Kummer extensions. The function fields are explicit.

## 1. The Tables

For $g \leq 50$ and for $q=2^{m}$ with $1 \leq m \leq 7$ and $q=3^{m}$ with $1 \leq m \leq 4$ we present tables which list values of $N_{q}(g)$ or an interval in which $N_{q}(g)$ lies. Note that $g=50$ is the largest value for which the actual value $N_{2}(g)$ is known. We therefore restricted to $g \leq 50$. Of course $N_{q}(0)=q+1$ for all $q$ and it is omitted from the tables. If the precise value of $N_{q}(g)$ is not known we either give an interval $[a, b]=\left[a_{q}(g), b_{q}(g)\right]$ or nothing. The meaning of the interval $[a, b]$ is: we know that there exists a curve with at least $a$ rational points over $\mathbb{F}_{q}$ and the best upper bound by Hasse-Weil, Serre, Ihara, Oesterlé or other means says $N_{q}(g) \leq b$. In the lion's share of the cases the value of $a$ represents a curve with exactly $a$ rational points; in about 20 cases (mostly constructed with method II) $a$ represents a lower bound for $N_{q}(g)$. Sometimes we entered no value. This happens if no curve with at least $[b / \sqrt{2}]$ rational points is known, i.e. if

$$
a_{q}(g)<\left[b_{q}(g) / \sqrt{2}\right] .
$$

The reason for this is that for $g \leq 50$ in many cases the upper bound $b_{q}(g)$ is Ihara's bound (1). Since the asymptotic bound (3) of Drinfeld-Vladut is approximately $1 / \sqrt{2}$ times the asymptotic Ihara bound (2) we think it is reasonable to put this qualification requirement for $g \leq 50$ to filter out curves which should be considered 'poor'.

Two main tables 'Table $p=2$ ' and 'Table $p=3$ ' present values of the function $N_{q}(g)$ or an interval in which $N_{q}(g)$ lies. In additional tables $q=x$ : sources we list the construction method of a curve producing the value of $a_{q}(g)$ and the source where this curve occurs first.

Remarks. i) For $q=2$ one can find explicit curves realizing the lower bound for $g \in\{5,6,7,8,9,12,13,14,15\}$ in [N-X2], for $g=10$ in [G-V7] and for $g=11$ in [N-X1]. For $q=3,4, g=4$ there are explicit curves in [N-X3].
ii) A result communicated to us by R. Schoof (see [G-V4]) gives values for the lower bound $a_{q}(g)$ for the pairs $(q=2, g \in\{26,32,33,40,46,47,48\}),(q=4, g \in$ $\{6,16,44,45\})$ and $(q=8, g \in\{16,23,45\})$.
iii) The modular curves $X(9), X(11)$ and $X(13)$ yield the results for $(q=$ $4, g \in\{10,26,50\})$ and $X(8), X(11)$ and $X(13)$ yield the results for $(q=9, g \in$ $\{5,26,50\})$.

The results collected in our tables represent the work of many mathematicians. We tried to give credit to whom it is due, but may have failed due to ignorance. A closer look at the tables will convince the reader that there is still ample room for improvement. The tables should be seen as an attempt to record the state of the art. If the reader knows an improvement of an entry we shall appreciate if he/she let us know so that we can update or correct the tables.
